A note on the theory $\text{SID}_{<\omega}$ of stratified induction

Florian Ranzi* Thomas Strahm**

Abstract

We introduce and analyse a theory of finitely stratified general inductive definitions over the natural numbers, $\text{SID}_{<\omega}$, and establish its proof-theoretic ordinal, $\varphi_{\varepsilon_0}(0)$. The definition of $\text{SID}_{<\omega}$ bears some similarities with D. Leivant’s ramified theories for finitary inductive definitions.

Keywords: Proof theory, inductive definitions, stratification.

1 Introduction

First-order theories that result from number theory by adding new predicate symbols $P$ and axioms for $P$ are used as a tool to investigate the proof-theoretic strength of various theories (consider [BFPS81] for example). In particular and with focus on the topic of this note, predicates $P^A$ may formalise for each positive arithmetical operator form $A$ a fixed-point $F_\Phi$ of the operator $\Phi: \mathcal{P}(\mathbb{N}) \to \mathcal{P}(\mathbb{N})$, where $\Phi$ is the intended interpretation of $A$ and $\mathcal{P}(\mathbb{N})$ is the power set of the natural numbers $\mathbb{N}$ (compare [Acz77a] for background information). A famous example of such a formalisation is the impredicative theory $\text{ID}_1$ that allows to axiomatise the least fixed-point $I_\Phi$ of such $\Phi$ by means of axioms for the closure property and the induction principle assigned to $P$; in the context of $\Phi$ this can be expressed by

\begin{align*}
\Phi(I_\Phi) &\subseteq I_\Phi \quad \text{(\text{\text{\Phi-Closure}})} \\
(\forall X \subseteq \mathbb{N}) (\Phi(X) &\subseteq X \to I_\Phi \subseteq X) \quad \text{(\text{\text{\Phi-Induction}})}
\end{align*}

and if considered as a definition of $I_\Phi$, its impredicative characterisation becomes apparent by the unrestricted quantification over subsets of $\mathbb{N}$. Furthermore, one can consider just any fixed-point $F_\Phi$, thus described by the single equation

\[ \Phi(F_\Phi) = F_\Phi \quad \text{(\text{\text{\Phi-Fixed-Point}})} \]

that is a consequence of (\text{\text{\Phi-Closure}}) and (\text{\text{\Phi-Induction}}).

A theory that formalises fixed-points over positive arithmetical operator forms $A$ is the theory $\overset{\sim}{\text{ID}}_1$, it was introduced in [Acz77b] and further analysed for the iterated case in [Fef82] and [JKSS99], using predicative methods. While $\overset{\sim}{\text{ID}}_1$ has no formalisation for (\text{\text{\Phi-Induction}}) at all, a theory that is predicatively reducible and axiomatises certain (so-called positive) instances of $\Phi(X) \subseteq X \to I_\Phi \subseteq X$ is the theory $\text{ID}^*_1$. It has been analysed in [Pro06] and [AR10], in particular $|\text{ID}^*_1| = |\text{ID}_1| = \varphi_{\varepsilon_0}(0)$ has been shown there for the proof-theoretic ordinal of $\text{ID}^*_1$.

The aim of this note is to investigate the proof-theoretic strength of a theory of stratified induction \( \text{SID}_{<\omega} \). It has a similar approach as in \( \text{ID}_1^* \), namely in the sense of formalising certain instances of (\( \Phi \)-Induction). In order to illustrate the differences, we need to consider the axioms of those two theories (precise formulations for \( \text{SID}_{<\omega} \) are given in section 2). Therefore let \( \mathcal{L}_{PA} \) be some usual formulation of the first-order language of Peano arithmetic \( PA \), augmented with countably many set-parameters (i.e., fresh unary relation symbols \( X \)) that are only used as place-holders in the sense described further below. A formula is called \( \text{arithmetical} \) if it is formulated in the language \( \mathcal{L}_{PA} \). For any arithmetical formula \( \mathfrak{A}(X,x) \) with a designated number variable \( x \) that may occur free in it (and that contains no other free number variable) and a designated set-parameter \( X \) occurring at most positively—i.e., \( \mathfrak{A}(X,x) \) is a positive operator form—let \( P^\mathfrak{A} \) be a distinguished new unary relation symbol not in \( \mathcal{L}_{PA} \). Then the language obtained by extending \( \mathcal{L}_{PA} \) with such new symbols \( P^\mathfrak{A} \) is used as the language \( \mathcal{L}_{ID} \) for the theories \( \text{ID}_1 \), \( \text{ID}_1^* \), and \( \text{ID}_1^* \). The first of these theories formalises (\( \Phi \)-Induction) by means of the axiom scheme

\[
(\forall x)(\mathfrak{A}(\{z:B\},x) \rightarrow B_z(x)) \rightarrow (\forall x)(P^\mathfrak{A}(x) \rightarrow B_z(x)) \tag{ID}
\]

where \( B \) can be any \( \mathcal{L}_{ID} \) formula and \( B_z(t) \) denotes for any \( \mathcal{L}_{PA} \) term \( t \) the substitution of \( z \) in \( B \) by \( t \), furthermore \( \mathfrak{A}(\{z:B\},x) \) expresses the straight-forward substitution of atomic formulas \( t \in X \) in \( \mathfrak{A}(X,x) \) by \( B_z(t) \).

While \( \text{ID}_1 \) has no instances of (ID), the theory \( \text{ID}_1^* \) allows for positive induction (\( \text{ID}^* \)), i.e., it contains instances of (ID) where \( B \) may contain \( P^\mathfrak{A} \) at most positively. The new theory \( \text{SID}_{<\omega} \) that we propose and investigate here is used to express a kind of \( \text{stratified induction} \) (over fixed-points) by admitting indexed copies of the above mentioned symbols \( P^\mathfrak{A} \), namely by replacing \( P^\mathfrak{A} \) with infinitely many distinguished new unary relation symbols \( P^\mathfrak{A}_n \) for \( 1 \leq n < \omega \) (i.e., \( P^\mathfrak{A}_1, P^\mathfrak{A}_2, \ldots \)). Hence, \( \text{SID}_{<\omega} \) has a different language than \( \text{ID}_1 \) and further has stratified induction (over fixed points) via the axiom scheme

\[
(\forall x)(\mathfrak{A}(\{z:B\},x) \rightarrow B_z(x)) \rightarrow (\forall x)(P^\mathfrak{A}_n(x) \rightarrow B_z(x)) \tag{SID}
\]

for \( 1 \leq n < \omega \) and with the restriction that \( B \) has to be a formula in this new language which may contain relation symbols \( P^\mathfrak{B} \) only if \( l < n \) (where \( \mathfrak{B} \) is some operator form).

Let \( \text{SID}_n \) denote the restriction of the theory \( \text{SID}_{<\omega} \) to formulas that contain at most the symbols \( P^\mathfrak{A}_l \) with \( l \leq n \). The theory \( \text{SID}_0 \) is just \( PA \) and the theory \( \text{SID}_1 \) is essentially a weakening of \( \text{ID}_1^* \) where (ID*) is further restricted in B to allow only arithmetical formulas. We will investigate the theories \( \text{SID}_n \) of \( \text{finitely stratified induction} \) and refer for the next question on the treatment of \( \text{transfinitely stratified induction} \) to [JP15]. In this note, we show how we can apply the proof-theoretic technique of asymmetric interpretation very neatly in order to gain proof-theoretic insight into this concept of stratified induction.

Aiming towards a characterisation of \( \text{SID}_{<\omega} \), notice that it is the same as \( \bigcup_{n<\omega} \text{SID}_n \) and that obviously \( \text{SID}_n \) embeds into \( \text{ID}^*_n \) for any \( n < \omega \). So we have for the proof-theoretic ordinal \( |\text{SID}_{<\omega}| \leq |\bigcup_{n<\omega} \text{ID}^*_n| = \Gamma_0 \), see [Can85]. We show in this note that actually \( |\text{SID}_{<\omega}| = |\text{ID}_1| \) holds. Since \( \text{ID}_1 \) trivially embeds into \( \text{SID}_{<\omega} \), it suffices to show that \( \varphi_{\epsilon_0}(0) = |\text{ID}_1| \) is an upper bound for \( |\text{SID}_{<\omega}| \), and this is done via an asymmetric interpretation combined with partial cut-elimination.
The approach of this article bears some similarities to D. Leivant’s proof-theoretic approach to computational complexity (cf. e.g. [Lei94]) which makes use of ramified theories over (finite) inductively generated free algebras. Here we treat ramified general inductive definitions over the natural numbers. W. Buchholz’s notes [Buc05] contributed to the presentation of the following material.

2 The theory $\text{SID}_{<\omega}$ of stratified induction

We are now going to render more precisely the notions given in the introduction.

Definition 2.1 (Preliminaries).

- As basic logical symbols of first-order predicate logic with equality, take the usual symbols $\neg, \land, \lor, \exists, =$, together with countably many (number) variables. We use $x, y, z$ as syntactic variables for those number variables, and for any kind of syntactic variables introduced here, we allow subscripts and vector notation.

- $\mathcal{L}_{\text{PA}}$ denotes the first-order language of Peano arithmetic $\text{PA}$ (with the usual function and relation symbols for primitive recursive functions and relations) plus set-parameters, i.e., countably many unary relation symbols. We use $X, Y, Z$ as syntactic variables for set-parameters.

- $\mathcal{L}_{\text{PA}}$ terms will be just called terms. We use $s, t$ as syntactic variables for terms and denote by $\text{TER}_0$ the set of closed terms. In case that $t$ is closed (i.e., does not contain a variable) we mean by $t^\mathbb{N}$ the numerical value of $t$, i.e., the valuation of $t$ in the standard model $\mathbb{N}$.

Consider a fixed language $\mathcal{L} \supseteq \mathcal{L}_{\text{PA}}$. We define $\mathcal{L}$ formulas as usual inductively from $\mathcal{L}$ and the basic symbols but with the restriction that the negation symbol $\neg$ is only allowed to occur in front of an atomic formula. We use $A, B, C, D$ as syntactic variables for $\mathcal{L}$ formulas. A literal is either an atomic formula or its negated version. In case of a compound formula $A$, its negation $\neg A$ stands for the translation of $A$ according to De Morgan’s laws and the law of double negation.

Moreover, we use capital Greek letters $\Gamma, \Delta, \Sigma$ as syntactic variables for $\mathcal{L}$ sequents, i.e., finite (possibly empty) lists of $\mathcal{L}$ formulas (e.g., $A_0, \ldots, A_k$) that are identified with finite sets (i.e., $\{A_0, \ldots, A_k\}$). Therefore, $\Gamma, A$ is understood as $\Gamma \cup \{A\}$ and accordingly $\Gamma, \Delta$ is identified with $\Gamma \cup \Delta$.

In order to stress that $A$ is an $\mathcal{L}$ formula, we write ambiguously $A \in \mathcal{L}$. Moreover, $A \rightarrow B$ abbreviates just $\neg A \lor B$. If an $\mathcal{L}$ formula is introduced as $A(z)$, this means that $A$ denotes this formula and that the variable $z$ may occur freely in $A$. We write $\text{FV}(A)$ for the set of free number variables of $A$. A formula is called arithmetical in case of $A \in \mathcal{L}_{\text{PA}}$.

Substitution of a variable $z$ in $A$ by a term $t$ is denoted by $A_z(t)$, or just by $A(t)$ in case $A$ has been introduced in the form $A(z)$.

Let $P$ be a unary relation symbol of $\mathcal{L}$ and $A$ an $\mathcal{L}$ formula. Then we say that $P$ occurs positively in $A$ if $A$ does not contain the negated formula $\neg P(t)$ for any term $t$. Moreover, we write often $t \in P$ instead of $P(t)$ and $t \notin P$ instead of $\neg P(t)$.

The axioms of

I. Number-theoretic and logical axioms:

Recall that

Definition 2.2.

Proof. For each

Definition 2.3.

From now on, let

Theorem 2.4

From now on, let

By ordinals we actually mean ordinals smaller than the first strongly-critical ordinal \( \Gamma_0 \), in particular we will work with the binary Veblen-function \( \varphi \). In fact, we will need only ordinals below \( \varphi_{\varepsilon_0}(0) \) and for most of the results even ordinals below \( \varepsilon_0 \) will suffice. We use small Greek letters \( \alpha, \beta, \gamma, \delta, \xi, \pi, \nu, \tau \) as syntactic variables for ordinals.

From now on, let \( X \) denote a fixed set-parameter. We call an arithmetical formula a positive (arithmetical) operator form if it contains \( X \) at most positively and if it contains at most one number variable. In order to stress the special role of such formulas, we use \( A, B \) as syntactic variables for those and consider them implicitly given as \( A(X, x) \) for some variable \( x \). In particular, we assume \( \text{FV}(A(X, x)) \subseteq \{ x \} \) here, while set-parameters distinct from \( X \) may still occur in \( A \).

Given a language \( \mathcal{L} \supseteq L_{\text{PA}} \) together with an \( \mathcal{L} \) formula \( B \) and a term \( t \), we write \( A\{z: B\}, t \) for the \( \mathcal{L} \) formula obtained from \( A \) by substituting any atomic formula \( X(s) \) with \( B_z(s) \) and any occurrence of \( x \) with \( t \), while a renaming of bound variables may be necessary as usual. In case \( B \) has been introduced as \( B(z) \), we write also \( A\{z: B(z)\}, t \) for \( A\{z: B\}, t \). Moreover, for unary relation symbols \( P \in \mathcal{L} \), we abbreviate \( A\{z: P(z)\}, t \) by \( A(P, t) \).

The proof-theoretic ordinal of a first-order theory \( T \) over a language \( \mathcal{L} \supseteq L_{\text{PA}} \) is denoted by \( |T| \). We refer to \([Poh09]\) for background information.

Definition 2.2. For each \( A \) and \( 1 \leq n < \omega \) let \( P^n_A \) denote a new and distinguished unary relation symbol. Furthermore, define for each \( n < \omega \):

\[
\mathcal{L}_0 := L_{\text{PA}} \quad \mathcal{L}_{n+1} := \mathcal{L}_n \cup \{ P^n_A : A \text{ is a positive operator form} \}
\]

From now on, let \( A, B, C, D \) range over formulas of the language \( \mathcal{L}_{<\omega} := \bigcup_{n<\omega} \mathcal{L}_n \).

Definition 2.3. For each \( n < \omega \), the theory \( \text{SID}_n \) with language \( \mathcal{L}_n \) consists of the following axioms.

I. Number-theoretic and logical axioms:
The axioms of PA with the scheme of complete induction for all \( \mathcal{L}_n \) formulas.

II. Stratified induction axioms for \( 1 \leq m \leq n \) and \( B(z) \in \mathcal{L}_{m-1} \):

\[
\forall x (A(B(z), x) \rightarrow B(x)) \rightarrow \forall x (x \in P^n_m \rightarrow B(x))
\]

III. Fixed-point axioms for \( 1 \leq m \leq n \):

\[
\forall x (A(P^n_m, x) \leftrightarrow x \in P^n_m)
\]

The theory \( \text{SID}_{<\omega} \) with language \( \mathcal{L}_{<\omega} \) is the collection \( \bigcup_{n<\omega} \text{SID}_n \). Furthermore, we also presume that a derivability notion \( \text{SID}_n \vdash A \) is given for each \( n < \omega \) and \( A \in \mathcal{L}_n \) via a standard first-order Hilbert-style predicate calculus. Accordingly, \( \text{SID}_{<\omega} \vdash A \) for \( A \in \mathcal{L}_{<\omega} \) just means that \( A \in \mathcal{L}_n \) and \( \text{SID}_n \vdash A \) hold for some \( n < \omega \).

Theorem 2.4 (Lower bound of \( |\text{SID}_{<\omega}| \)).

\[
\widehat{\Gamma}_1 \vdash A \quad \Longrightarrow \quad \text{SID}_1 \vdash A
\]

holds for each \( A \in L_{\text{PA}} \). Therefore \( \varphi_{\varepsilon_0}(0) \leq |\text{SID}_{<\omega}| \).

Proof. Recall that \( |\widehat{\Gamma}_1| = \varphi_{\varepsilon_0}(0) \) and notice that \( \widehat{\Gamma}_1 \) is essentially \( \text{SID}_1 \) without \( \textbf{II} \) from its definition. \( \square \)
Strategy for the upper bound of $\text{SID}_{<\omega}$. We will work with infinitary proof systems $\text{SID}^\omega_n$ with $n < \omega$ that are suitable for partial cut elimination, asymmetric interpretation, and in case of $n = 0$ full predicative cut-elimination. The steps to reach the main result of section 4 will be the following:

1. Unary relation symbols $Q^\xi_{\mathfrak{A}}$ for each $\mathfrak{A}$ and $\xi$ are added to the language.

2. For each $n < \omega$, set up an infinitary proof-system $\text{SID}^\omega_n$. For $n > 0$, we obtain a useful result on partial cut elimination (p.c.e.), while for the case $n = 0$, we can even achieve full predicative cut-elimination (f.c.e.).

3. Asymmetric interpretation (a.i.) is used to establish the connection between the systems $\text{SID}^\omega_{n+1}$ and $\text{SID}^\omega_n$ for any $n < \omega$, given that we deal with derivations where we partially removed cuts first. In particular, the symbols $P^\mathfrak{A}_{n+1}$ are interpreted by $Q^\xi_{\mathfrak{A}}$ for suitable $\xi$.

4. The theme is to start with a formal derivation in $\text{SID}_{n+1}$ of an arithmetical formula $A$, embed it into $\text{SID}_{n+1}^\omega$ such that the proof complexity stays below $\varepsilon_0$, combine a p.c.e. followed by an a.i. iteratively, and end up with a derivation in $\text{SID}_0^\omega$ with proof complexity still below $\varepsilon_0$. Then f.c.e. yields the desired sharp bound $\varphi_{\varepsilon_0}(0)$ for $|\text{SID}_{<\omega}|$ via a standard boundedness argument:

$$\text{SID}_{n+1} \xrightarrow{\text{embed}} \text{SID}_{n+1}^\omega \xrightarrow{\text{p.c.e.}} \text{SID}_n^\omega \xrightarrow{\text{a.i.}} \text{SID}_{n+1}^\omega \xrightarrow{\text{\ldots}} \text{SID}_0^\omega \xrightarrow{\text{f.c.e.}} \text{SID}_0^\omega$$

Besides the care needed to maintain a proof-complexity below $\varepsilon_0$, we also have to cope with the fact that in general an infinitary proof system may yield derivations whose cuts cannot be globally bounded. In particular for our iterative use of p.c.e. that started with embedding a formal derivation (e.g., from $\text{SID}_{n+1}^\omega$ into $\text{SID}_0^\omega$), we depend on the method of a.i. to provide always a derivation whose cut-formulas are bounded by a finite ordinal. To guarantee this, we shall fix a finite ordinal $\ell$ and restrict the derivability relation for $\text{SID}_n^\omega$ with $n > 0$ such that the cut-formulas have to be globally bounded by $\ell$.

3 The infinitary proof system $\text{SID}_n^\omega$ for $n < \omega$

Convention. For the rest of this section, we fix some finite ordinal $\ell$. In particular, we will define the derivability relation for the proof systems $\text{SID}_n^\omega$ such that $\ell$ globally bounds the length of the cut-formulas that are allowed in an application of a cut-rule if $n > 0$. Compare the proof of lemma 3.9 to see why this bound should not hold for the case $n = 0$.

Definition 3.1. Let $Q^\xi_{\mathfrak{A}}$ be a fresh unary relation symbol for each $\mathfrak{A}$ and $\xi$. For each $n < \omega$, let $L_n^\omega := L_n \cup \{ Q^\xi_{\mathfrak{A}} : \xi < \Gamma_0 \ & \ & \mathfrak{A} \text{ is a positive operator form} \}$. In the following, let $A, B, C, D$ range over formulas of the language $L_{<\omega} := \bigcup_{n<\omega} L_n^\omega$.

Definition 3.2. The length $\text{lh}(A)$ of a formula $A$ is defined as the number of basic logical symbols that occur in $A$. In particular, $\text{lh}(A) = \text{lh}(A_s(t))$ holds for all terms $t$. 

5
Definition 3.3. Let \( \text{rk}_0(A) := 0 \) for each \( A \in \mathcal{L}_0^\infty \). For \( 1 \leq n < \omega \), we say that \( A \in \mathcal{L}_n^\infty \) is \( n \)-atomic if \( A \in \mathcal{L}_{n-1}^\infty \) or if it is a literal of the form \( t \in P_n^\infty \) or \( t \not\in P_n^\infty \).

The \( n \)-rank \( \text{rk}_n(A) \) is defined for \( 1 \leq n < \omega \) and formulas \( A \in \mathcal{L}_n^\infty \) by

\[
\text{rk}_n(A) := \begin{cases} 
0 & \text{if } A \text{ is atomic, or otherwise} \\
\max(\text{rk}(B), \text{rk}(C)) + 1 & \text{if } A = B \land C \text{ or } A = B \lor C \\
\text{rk}(B) + 1 & \text{if } A = \forall x B \text{ or } A = \exists x B
\end{cases}
\]

The ordinal-rank \( \text{rk}(A) \) is defined for formulas \( A \in \mathcal{L}_{<\omega}^\infty \) by

\[
\text{rk}(A) := \begin{cases} 
0 & \text{if } A \text{ is a literal and } A \in \mathcal{L}_{<\omega} \\
\omega \cdot \xi & \text{if } A = t \in Q_{<\xi}^\infty \text{ or } A = t \not\in Q_{<\xi}^\infty \\
\max(\text{rk}(B), \text{rk}(C)) + 1 & \text{if } A = B \land C \text{ or } A = B \lor C \\
\text{rk}(B) + 1 & \text{if } A = \forall x B \text{ or } A = \exists x B
\end{cases}
\]

Furthermore for \( 1 \leq n < \omega \) and \( A \in \mathcal{L}_n^\infty \), we write \( A \in \text{Pos}_n \) to denote that \( P_n^\infty \) occurs at most positively in \( A \) for every \( \mathfrak{A} \), and we write \( A \in \text{Neg}_n \) to denote \( \neg A \in \text{Pos}_n \).

Remark. For \( A \in \mathcal{L}_n^\infty \) and \( 1 \leq n < \omega \), we have that \( \text{lh}(A) < \ell \) implies \( \text{rk}_n(A) < \ell \), and that \( \text{rk}_n(A) \neq 0 \) implies that \( A \) is not a literal.

Definition 3.4. For each \( n < \omega \), the infinitary Tait-style proof system \( \text{SID}_n^\infty \) with language \( \mathcal{L}_n^\infty \) is defined by means of the following inferences (i.e., axioms and inference rules). \( \text{SID}_n^\infty \) shall derive \( \mathcal{L}_n^\infty \) sequents that consist of closed formulas only, therefore we assume in this definition that the sequents of the axioms and the sequents that occur in the premiss of a rule consist of closed \( \mathcal{L}_n^\infty \) formulas only. Note that the inference rules \( (\forall x A) \) and \( (\forall t \notin Q_{<\tau}^\infty) \) have infinitely many premises.

I. Number-theoretic and logical axioms:
\[
\Gamma, A \quad \text{if } A \text{ is a true } \mathcal{L}_{PA} \text{ literal without set-parameters} \\
\Gamma, A(s), \neg A(t) \quad \text{if } s^\mathfrak{A} = t^\mathfrak{A} \text{ and } A(z) \in \mathcal{L}_n \text{ is atomic}
\]

II. Stratified induction axioms for each \( 1 \leq m \leq n \) and \( B(z) \in \mathcal{L}_{m-1} \):
\[
\Gamma, \exists x (\mathfrak{A}(B(z), x) \land \neg B(x)), t \not\in P_m^\infty, B(t)
\]

III. Fixed-point rules for \( 1 \leq m \leq n \):
\[
\Gamma, \mathfrak{A}(P_m^\infty, t) \quad (\text{Fix}_t \in P_m^\infty) \quad \Gamma, \neg \mathfrak{A}(P_m^\infty, t) \quad (\text{Fix}_t \notin P_m^\infty)
\]

IV. Predicative rules:
\[
\Gamma, A \quad (\forall A \in B) \quad \Gamma, B \quad (\forall B \in A) \\
\Gamma, A \land B \quad (\forall A \land B) \\
\Gamma, A(x(t)) \quad (\text{Fix}_x \in A) \quad \Gamma, A(t) \quad (\text{Fix}_t \notin A)
\]

...
V. Cut rule:

\[
\frac{\Gamma, C \quad \Gamma, \neg C}{\Gamma} \quad (\text{Cut}_C)
\]

For each of the above mentioned inferences, we define the notions side formula, minor formula, and main formula as usual. In particular, (Cut\(_C\)) has no main formulas, the axioms in I and II do not have minor formulas, and for every inference the formulas in the sequent \(\Gamma\) are the side formulas.

**Definition 3.5.** The derivability notion \(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma\) for \(n, r < \omega\) is defined inductively on \(\alpha\):

- \(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma\) holds for all \(\alpha, \rho,\) and \(r < \omega\) if \(\Gamma\) is an axiom of \(\text{SID}^\infty_n\).

- \(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma\) holds if there is a rule of \(\text{SID}^\infty_n\) in III or IV such that \(\Gamma\) is its conclusion and \(\text{SID}^\infty_n \vdash_{\rho, r}^{\alpha_i} \Gamma_i\) holds for each of its premisses \(\Gamma_i\) with some \(\alpha_i < \alpha\).

- \(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma\) holds if \(\text{SID}^\infty_n \vdash_{\rho, r}^{\alpha_0} \Gamma, C\) and \(\text{SID}^\infty_n \vdash_{\rho, r}^{\alpha_1} \Gamma, \neg C\) hold for some \(\alpha_0, \alpha_1 < \alpha\) and we have \(\text{rk}(C) < \rho, \text{rk}_n(C) < r,\) and in case of \(n > 0\) also \(\text{lh}(C) < \ell\).

Moreover, \(\text{SID}^\infty_n \vdash_{\rho, r}^{< \alpha} \Delta\) means that \(\text{SID}^\infty_n \vdash_{\rho, r}^{\alpha_0} \Gamma\) holds for some \(\alpha_0 < \alpha\).

**Remark.** Recalling the end of section 2 where we explained the strategy of this article, we notice here that for \(n > 0\), the condition \(\ell\) can be preserved here.

**Lemma 3.6** (Weakening).

\(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma \land \alpha \leq \beta \land \rho \leq \eta \land r \leq k \land \Gamma \subseteq \Delta \implies \text{SID}^\infty_n \vdash_{\eta, k}^\beta \Delta\)

**Proof.** By a straightforward induction on \(\alpha\). Notice that the condition concerning \(\ell\) can be preserved here. \(\Box\)

**Remark 3.7.** \(\text{SID}^\infty_n \vdash_{\rho, r}^\alpha \Gamma\) with \(\rho = 0\) or \(r = 0\) implies \(\text{SID}^\infty_n \vdash_{0, 0}^\alpha \Gamma\). Notice also that \(\text{SID}^\infty_0 \vdash_{\rho, 0}^\alpha \Gamma\) implies \(\text{SID}^\infty_0 \vdash_{\rho, 0}^\alpha \Gamma\) since \(\text{rk}_0(A) = 0\) for each \(A \in \mathcal{L}_0^\infty\). Furthermore, we notice that in the following we will not mention every use of lemma 3.6 explicitly.

3.1 Partial and full cut-elimination

**Lemma 3.8.** For each \(1 \leq n < \omega\) and \(C \in \mathcal{L}_n^\infty\) with \(\text{lh}(C) < \ell\), we have

\[
\text{rk}_n(C) = 1 + r \land \text{SID}^\infty_n \vdash_{\rho, 1 + r}^\alpha \Gamma, C \land \text{SID}^\infty_n \vdash_{\rho, 1 + r}^\beta \Gamma, \neg C \implies \text{SID}^\infty_n \vdash_{\rho, 1 + r}^{\alpha \# \beta} \Gamma
\]
Proof. By induction on $\alpha \# \beta$ and the following case distinction.
1. $C$ or $\neg C$ is not among the main formulas of the last inference of $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r} \Gamma, C$ or $\text{SID}_n^\infty \vdash^\beta_{\rho,1+r} \Gamma, \neg C$, respectively: The claim follows immediately from the I.H. or, in case of an axiom, by reapplying the inference with suitable side formulas.
2. Otherwise, we notice first that $\text{rk}_n(C) \neq 0$, hence $C$ is not $n$-atomic and only the following cases are possible:
   2.1. $C = C_0 \lor C_1$ and $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r} \Gamma, C, C_0$ for some $\alpha_0 < \alpha$: Then we also get $\text{SID}_n^\infty \vdash^\beta_{\rho,1+r} \Gamma, \neg C_0$ for some $\beta_0 < \beta$, so by I.H. we get $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r}\Gamma, C_0$ and $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r}\Gamma, \neg C_0$. Since $\alpha_0 \# \beta_0$, $\alpha \# \beta_0 < \alpha \# \beta$, $\text{rk}_n(C_0) < \text{rk}_n(C) = 1 + r$, and also $\text{lh}(C_0) < \text{lh}(C)$ hold, we can apply $(\text{Cut}_{C_0})$ in order to obtain $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r}\Gamma, C, C_1$ or $C = C_0 \land C_1$ holds treated similarly.
   2.2. $C = \exists x D$ or $C = \forall x D$: The claim follows similar to the previous case, notice that $\text{lh}(D(x(t))) = \text{lh}(D) < \text{lh}(C)$ holds for any term $t$.

Lemma 3.9. For each $C \in L_0^\infty$, we have
\[
\text{rk}(C) = \rho \quad \& \quad \text{SID}_0^\infty \vdash^\alpha_{\rho,r} \Gamma, C \quad \& \quad \text{SID}_0^\infty \vdash^\beta_{\rho,r} \Gamma, \neg C \implies \text{SID}_0^\infty \vdash^\alpha_{\rho,r} \Gamma
\]

Proof. By induction on $\alpha \# \beta$ and almost literally as lemma 3.8 because of a similar behaviour of the $n$-rank $\text{rk}_n$ and the ordinal-rank $\text{rk}$ in combination with the built-up of formulas. The following two special situations illustrate the advantage of the ordinal-rank $\text{rk}$ and why this does not work for $\text{SID}_n^\infty$ with $n > 0$. Assume that both $C$ and $\neg C$ are among the main formulas of the last inference.
1. $C$ is the main formula of an axiom: Then it can only be due to an instance of $I$, so $C$ and $\neg C$ are $L_{PA}$ literals. If $C = Y(s)$ for some set-parameter $Y$ and term $s$, then we have $\neg Y(t), Y(t') \in \Gamma$ for some $t, t'$ with $t^N = s^N = t'^N$, and hence $\Gamma$ is already an instance of $I$. Otherwise, if $C$ does not contain a set-parameter, the claim again follows easily from $I$.
2. $C = t \in Q^<\alpha_X$ with $\text{SID}_0^\infty \vdash^\alpha_{\rho,r} \Gamma, C, \Box(Q^<\xi_X, t)$ for some $\xi < \tau$ and $\alpha_\xi < \alpha$: Now $\rho = \omega \cdot \tau$ and $\neg C = t \notin Q^<\tau_X$. Because of the definition of $\text{SID}_0^\infty$, we do not have $\text{SID}_0^\infty \vdash^\beta_{\rho,r} \Gamma, \neg C$ due to a logical axiom and hence $\neg C$ must be the main formula of $(\bigwedge_{t \notin Q^<\tau_X})$. Then we have $\text{SID}_0^\infty \vdash^\beta_{\rho,r} \Gamma, \neg C, \neg \Box(Q^<\xi_X, t)$ available with $\beta_\xi < \beta$ for every $\xi < \tau$, so the claim follows very similar as in the proof of lemma 3.8. Notice that in the setting of $\text{SID}_n^\infty$, we do not have to guarantee $\text{lh}(\Box(Q^<\xi_X, t)) < \ell$, and that we have $\text{rk}(\Box(Q^<\xi_X, t)) < \omega \cdot (\xi + 1) \leq \rho$ because of $\xi < \tau$.

Theorem 3.10 (Cut-elimination).
(a) Partial cut-elimination: $\text{SID}_n^\infty \vdash^\alpha_{\rho,1+r} \Gamma$ implies $\text{SID}_n^\infty \vdash^\omega_n(\alpha)_{\rho,1} \Gamma$ for each $1 \leq n < \omega$, where $\omega_0(\alpha) := \alpha$ and $\omega_{k+1}(\alpha) := \omega(\omega_k(\alpha))$.
(b) Full predicative cut-elimination: $\text{SID}_0^\infty \vdash^\alpha_{\gamma^+,\omega^+} \Gamma$ implies $\text{SID}_0^\infty \vdash^\varphi_1(\alpha)_{\gamma,1} \Gamma$.

Proof. The theorem follows from the previous lemmas by a standard argument, and we refer to [Poh09] for details.
3.2 Asymmetric interpretation

**Convention.** We fix $n < \omega$ for this subsection and will only deal with the proof systems $\text{SID}_n^\omega$ and $\text{SID}_n^\omega$.

**Definition 3.11.** For $L_n^\omega$ formulas $A$, $L_n^\omega$ sequents $\Gamma$, and ordinals $\xi, \zeta_1, \ldots, \zeta_k$, we write

\[ A^\xi \quad \text{for the } L_n^\omega \text{ formula that is obtained from } A \text{ by substituting any} \]

\[ \Gamma^\xi \quad \text{for the } L_n^\omega \text{ sequent obtained from } \Gamma \text{ by substituting every occurring} \]

formula $A$ with $A^\xi$, and if $\Gamma$ is explicitly given as a list $A_1, \ldots, A_k$, we write

\[ [\Gamma]^{\xi_1, \ldots, \xi_k} \quad \text{for the } L_n^\omega \text{ sequent } A_1^{\xi_1}, \ldots, A_k^{\xi_k} \]

**Lemma 3.12.**

(a) $\text{SID}_n^\omega \vdash_{\rho, r} \Gamma, B(s_1), \neg B'(s_2)$ for each $s_1, s_2$ with $s_1^N = s_2^N$ implies that for each $t_1, t_2$ with $t_1^N = t_2^N$ also $\text{SID}_n^\omega \vdash_{\rho, r} \neg^2 \cdot \text{rk}(\mathfrak{A})$ $\Gamma, \mathfrak{A}(B(z), t_1), \neg \mathfrak{A}(B'(z), t_2)$ holds.

(b) $s^N = t^N$ and $\nu \leq \pi$ imply $\text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(s) \in Q_\mathfrak{A}^{\leq \pi}, s \notin Q_\mathfrak{A}^{\leq \nu}$.

(c) $s^N = t^N$ and $A(z) \in L_n^\omega$ imply $\text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(A(s), t)$, $\neg A(t)$

(d) $B(z) \in L_n$ implies $\text{SID}_n^\omega \vdash_{0, 0} \exists x(\mathfrak{A}(B(z), x) \land \neg B(x)), t \notin Q_\mathfrak{A}^{\leq \pi}, B(t)$.

**Proof.** Statement (a) is proven by a straightforward induction on $\text{rk}(\mathfrak{A}) < \omega$ and we leave the proof to the reader. Statement (b) is proven by induction on $\nu$: The case $\nu = 0$ follows from $(\bigwedge_{t \in Q_\mathfrak{A}^{\leq \pi}} \mathfrak{A}(s^N, t))$. If $\nu > 0$, the I.H. and (a) yield $\text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(s^N, t)$, $\neg \mathfrak{A}(s^N, t)$ for all $\xi < \nu$. Since $\nu \leq \pi$, the claim follows from $(\bigvee_{t \leq Q_\mathfrak{A}^{\leq \pi}})$ and $(\bigwedge_{s \notin Q_\mathfrak{A}^{\leq \nu}})$, and notice that $\mathfrak{A} \in L_{PA}$ implies $\text{rk}(\mathfrak{A}) < \omega$ and hence $\omega \cdot \xi + 2 \cdot \text{rk}(\mathfrak{A}) + 1 < \omega \cdot (\xi + 1) \leq \omega \cdot \nu$ holds for all $\xi < \nu$. Statement (c) is proven by a straightforward induction on $\text{rk}(\mathfrak{A})$, and we leave the proof to the reader, noticing that (b) is used for the case that $A$ is of the form $r \in Q_\mathfrak{A}^{\leq \xi}$. Finally, statement (d) is proven by induction on $\pi$ and we let $D := \exists x(\mathfrak{A}(B(z), x) \land \neg B(x))$. If $\pi = 0$, we immediately get $\text{SID}_n^\omega \vdash_{0, 0} D, B(t), t \notin Q_\mathfrak{A}^{\leq \pi}$. If $\pi > 0$, we first get

\[ \text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(s^N, t), \neg \mathfrak{A}(s^N, t) \]

by I.H. for all $\xi < \pi$ and all $t$. Using (a) with (c) and (e) with $B(t)$ yields

\[ \text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(B(z), t), \neg \mathfrak{A}(Q_\mathfrak{A}^{\leq \xi}, t) \]

\[ \text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(Q_\mathfrak{A}^{\leq \xi}, t), B(t), \neg B(t) \]

Since $B(t) \in L_n$, we have $\text{rk}(\mathfrak{A}) < \omega$ and hence we get for some $m < \omega$

\[ \text{SID}_n^\omega \vdash_{0, 0} \mathfrak{A}(B(z), t) \land \neg B(t), \neg \mathfrak{A}(Q_\mathfrak{A}^{\leq \xi}, t), B(t) \]

Using $(\bigvee_{D})$ and that $\omega \cdot \xi + m + 1 < \omega \cdot (\xi + 1) \leq \omega \cdot \tau$ holds for each $\xi < \tau$, the claim follows with an $(\bigwedge_{t \in Q_\mathfrak{A}^{\leq \tau}})$ inference. 

\[ \square \]
Theorem 3.14 (Asymmetric interpretation). Assume that we have
\[ \text{SID}_{n+1} \vdash_{\rho \cdot \pi} \Delta^- \cup \Delta^+ \]
for some \( \Delta^- \subseteq \text{Neg}_{n+1} \) and \( \Delta^+ \subseteq \text{Pos}_{n+1} \). Let \( \nu \) and \( \pi \) be given such that \( \pi = \nu + 2^\alpha \) and \( \rho \leq \omega \cdot \pi \) hold, then we have
\[ \text{SID}_{n+1} \vdash_{\rho \cdot \pi} \omega \cdot \pi \cdot \nu \cdot \Delta^- \cup \Delta^+ \]
Proof. By induction on \( \alpha \) and a case distinction for the last inference.
1. Axioms in I: In case of \( t \in P^\alpha_{n+1} \) with \( s \not\in P^\alpha_{n+1} \) and \( s^N = t^N \), we can use (b) in lemma 3.12 for \( t \in Q^\alpha_3 \) and \( s \not\in Q^\alpha_3 \). The other cases are trivial by taking appropriate instances of the corresponding axiom schemes.
2. Axioms in II: If we have an instance for some \( P^\alpha_m \) with \( 1 \leq m \leq n \), the axiom can be reused immediately. Otherwise it is an instance for some \( P^\alpha_{n+1} \), and then the claim follows by using (d) in lemma 3.12 for \( Q^\alpha_3 \).
3. (CutC) with \( \text{rk}(C) < \rho \leq \omega \cdot \pi \) and \( \text{rk}_{n+1}(C) = 0 \) (and also \( \text{lh}(C) < \ell \)):
   a. If \( C \) is of the form \( t \in P^\alpha_{n+1} \) (or \( t \not\in P^\alpha_{n+1} \)): We have \( \text{SID}_{n+1} \vdash_{\rho,1} \Delta^- \cup \Delta^+, t \in P^\alpha_{n+1} \) and
   \[ \text{SID}_{n+1} \vdash_{\rho,1} \omega \cdot \pi \cdot \nu \cdot \Delta^- \cup \Delta^+, t \not\in P^\alpha_{n+1} \]
   for some \( \alpha_0, \alpha_1 < \alpha \). The I.H. yields with \( \nu \) and \( \pi_0 := \nu + 2^\alpha_0 \)
   \[ \text{SID}_{n+1} \vdash_{\rho,1} \omega \cdot \pi_0 \cdot \Delta^- \cup \Delta^+, t \in Q^\pi_{\alpha_0} \]
   and it also yields with \( \pi_0 \) and \( \pi_1 := \pi_0 + 2^\pi_1 \)
   \[ \text{SID}_{n+1} \vdash_{\rho,1} \omega \cdot \pi_1 \cdot \Delta^- \cup \Delta^+, t \not\in Q^\pi_{\alpha_0} \]
   After some weakening and applying lemma 3.13 (using in particular \( \nu < \pi_0 \) and \( \pi_1 = \pi_0 + 2^\pi_1 \leq \nu + 2^\alpha = \pi \)), the claim follows by (Cut\( \mathcal{E}_{\text{Q}^\pi_{\alpha_0}} \)) since we have \( \text{rk}(t \in Q^\pi_{\alpha_0}) = \omega \cdot \pi_0 < \omega \cdot \pi \), \( \text{rk}_n(t \in Q^\pi_{\alpha_0}) = 0 \), and in case of \( n > 0 \), we also have \( \text{lh}(t \in Q^\pi_{\alpha_0}) = \text{lh}(C) < \ell \).
3.2. Otherwise $C \in \mathcal{L}_n^\infty$: First notice that we have $\text{rk}_n(C) \leq \text{lh}(C) < \ell$, so we can use the I.H. and then reuse $(\text{Cut}_C)$ in $\text{SID}_n^\infty$ to obtain the claim.

4. Fixed-point rules in $\text{III}$:

4.1. $(\text{Fix}_{t \in P^0_{n+1}}):$ We have $\text{SID}_{n+1}^\infty \vdash_{\alpha_0}^\infty \Delta^-, \Delta^+, \mathfrak{A}(P^0_{n+1}, t)$ and $\mathfrak{A}(P^0_{n+1}, t) \in \text{Pos}_{n+1}$ for some $\alpha_0 < \alpha$, and hence the I.H. with $\nu$ and $\pi_0 := \nu + 2\alpha_0 < \pi$ yields $\text{SID}_{n}^\infty \vdash_{\omega-\pi_0, \ell}^\infty [\Delta^-]^{\nu}, [\Delta^+]^\pi, \mathfrak{A}(Q^\infty_\beta, t)$. Then the claim follows from $(\bigvee_{t \in Q^\infty_\beta})$, lemma 3.13, and some weakening.

4.2. $(\text{Fix}_{t \in P^1_{n+1}}):$ We have $\text{SID}_{n+1}^\infty \vdash_{\alpha_0}^\infty \Delta^-, \Delta^+, -\mathfrak{A}(P^0_{n+1}, t)$ and $-\mathfrak{A}(P^0_{n+1}, t) \in \text{Neg}_{n+1}$ for some $\alpha_0 < \alpha$, so we get with $\pi_0 := \nu + 2\alpha_0$ by the I.H.

$$\text{SID}_{n}^\infty \vdash_{\omega-\pi_0, \ell}^\infty [\Delta^-]^{\nu}, [\Delta^+]^\pi, -\mathfrak{A}(Q^\infty_\beta, t)$$

and hence by lemma 3.13 and some weakening, we get for each $\xi < \nu$

$$\text{SID}_{n}^\infty \vdash_{\omega-\pi_0, \ell}^\infty [\Delta^-]^{\nu}, [\Delta^+]^\pi, -\mathfrak{A}(Q^\infty_\beta, t)$$

By using $(\bigwedge_{t \in Q^\infty_\beta})$, the claim follows.

4.3. $(\text{Fix}_{t \in P^0_{n+1}})$ or $(\text{Fix}_{t \in P^1_{n+1}})$ for some $1 \leq m \leq n$: We can apply the I.H. for the premise and reuse the rule because it is available in $\text{SID}_{n}^\infty$ and its minor formulas do not contain $P^0_{n+1}$.

5. Predicative rules in $\text{IV}$: Use the I.H. and repeat the rule with an appropriate instance.

**Remark.** An inspection of the proof of theorem 3.14 yields that in case of $\rho = 0$, we even obtain $\text{SID}_{n}^\infty \vdash_{\omega, \rho} [\Delta^-]^{\nu}, [\Delta^+]^\pi$ in the conclusion of theorem 3.14. We do not need this stronger result, though.

### 3.3 Arithmetical derivability

**Theorem 3.15** (Arithmetical derivability). Let $\Gamma \subseteq \mathcal{L}_{PA}$ and $r, n < \omega$. If $\text{SID}_{n}^\infty \vdash_{\rho, r}^\infty \Gamma$ holds for some $\rho < \varepsilon_0$, then $\text{SID}_{n+1}^\infty \vdash_{\eta, r}^\infty \Gamma$ holds for some $\eta < \varepsilon_0$.

**Proof.** By induction on $n$. The case $n = 0$ is clear (see remark 3.7). We can also assume $r > 0$ w.l.o.g. and get $\text{SID}_{n}^\infty \vdash_{\rho, r}^\infty \Gamma$ by theorem 3.10.(a). Now theorem 3.14 yields $\text{SID}_{n-1}^\infty \vdash_{\eta, \ell}^\infty \Gamma$ for some $\eta < \varepsilon_0$ and hence the claim by the I.H.

### 4 The upper bound of $\text{SID}_{< \omega}$

**Theorem 4.1.** If $\text{SID}_{n} \vdash A$ for a closed $\mathcal{L}_n$ formula $A$, then there is an $\ell < \omega$ such that the derivability relation for $\text{SID}_{n}^\infty$ and this $\ell$ yields $\text{SID}_{n}^\infty \vdash_{\ell, \ell}^\infty A$.

**Proof.** As usual and inductively with respect to the underlying derivability notion $\text{SID}_{n} \vdash A$. Notice that complete induction can be proven by use of the infinitary inference rule $(\bigwedge_{x \in B})$ and that no inferences are needed that involve symbols of the form $Q^\infty_\beta$ when inductively translating from $\text{SID}_{n} \vdash A$ to the proof-system $\text{SID}_{n}^\infty$ (hence cuts of finite rank $\ell$ are sufficient).
Corollary 4.2. $|\text{SID}_{<\omega}| \leq \varphi_{\varepsilon_0}(0)$.

Proof. For any closed arithmetical formula $A$ with $\text{SID}_n \vdash A$, we know from theorem 4.1 that $\text{SID}_{n}^{\omega} \vdash \varphi_{\varepsilon_0}(\alpha)$ holds for some $\alpha < \omega$. According to theorem 3.15, this means $\text{SID}_{0}^{\omega} \vdash \varphi_{\varepsilon_0}(\alpha)$ for some $\alpha < \omega$. By weakening we have $\text{SID}_{0}^{\omega} \vdash \varphi_{\varepsilon_0}(\alpha)$ for some $\alpha < \omega$. Finally, we get $|\text{SID}_{<\omega}| \leq \varphi_{\varepsilon_0}(0)$ by a standard boundedness argument. 

5 Concluding remarks

We finish this note on the theory $\text{SID}_{<\omega}$ of finitely stratified induction over fixed-points with some remarks on the proof-theoretic methods that we applied here and the generalisation to transfinite stratified induction. In this context, an immediate question is the relation of transfinite stratification to the iteration of fixed-point definitions. We established the connection of $\text{SID}_{<\omega}$ to the non-iterated theory $\text{ID}_1$ and will now briefly explain the concept of (finite) iteration of fixed-point definitions: Since $\text{ID}_1$ is based on positive operator forms $\mathfrak{A}_1$ that are formulated in the language $\mathcal{L}_{PA}$, the theory $\hat{\text{ID}}_2$ is based on positive operator forms $\mathfrak{A}_2$ that are formulated in the language $\mathcal{L}_{1}$ (i.e., $\hat{\text{ID}}_2$ axiomatises fixed-points of $\mathfrak{A}_2$ by means of new unary relation symbols $P_{\mathfrak{A}_2}$ for each such $\mathfrak{A}_2$, resulting in the language $\mathcal{L}_{\hat{\text{ID}}_2}$ of $\hat{\text{ID}}_2$). This is similarly defined for $\text{ID}_n$ with arbitrary $2 < n < \omega$, and it further extends to transfinite iterations of fixed-point definitions $\hat{\text{ID}}_n$. As remarked in the introduction, we know for instance that $|\text{ID}_\beta^*| = |\text{ID}_\beta|$ holds for any ordinal $\beta$, and we refer to [JKSS99] and [Pro06] for details on results and definitions.

Comparison with the proof-theoretic methods for $\hat{\text{ID}}_n$ Considering only the case $n = 2$ and the reduction of $\hat{\text{ID}}_2$ to $\hat{\text{ID}}_1$, we first notice that similar methods (e.g., asymmetric interpretation) are used as in the reduction of $\text{SID}_2$ to $\text{SID}_1$ but with the difference that $|\hat{\text{ID}}_1| < |\hat{\text{ID}}_2|$ holds and that we actually established $|\text{SID}_1| = |\text{SID}_2|$ here. This is due to the following observation: Without going into too many details, let $\hat{\text{ID}}_2$ and $\hat{\text{ID}}_1$ be the infinitary proof-systems assigned to $\hat{\text{ID}}_2$ and $\hat{\text{ID}}_1$, respectively, which are defined in a similar way as the infinitary proof-systems in section 3. The difference is that stratified induction axioms are missing and that for $\hat{\text{ID}}_2^\omega$, we have fixed-point rules

$$
\frac{\Gamma, \mathfrak{A}_2(P_{\mathfrak{A}_2}, t)}{\Gamma, t \in P_{\mathfrak{A}_2}} \quad \text{(Fix}_{t \in P_{\mathfrak{A}_2}} \text{)}
$$

for positive operator forms $\mathfrak{A}_2(X, x) \in \mathcal{L}_{1}$ that may contain symbols $P_{\mathfrak{A}_1}$ for positive operator forms $\mathfrak{A}_1 \in \mathcal{L}_0(= \mathcal{L}_{PA})$ in arbitrary position. This is not the case for $\text{SID}_2$ where the operator form is arithmetical. As remarked above, the reduction from $\hat{\text{ID}}_2$ to $\hat{\text{ID}}_1$ uses asymmetric interpretation of $\text{SID}_2$ in $\text{SID}_1^\omega$, therefore $\text{SID}_1^\omega$ has for example predicative rules of the form

$$
\frac{\Gamma, \mathfrak{A}_2(Q_{\mathfrak{A}_2}, t)}{\Gamma, t \in Q_{\mathfrak{A}_2}} \quad \text{(Fix}_{t \in P_{\mathfrak{A}_2}} \text{)} \quad \text{for} \quad \xi < \tau
$$

(\#)

with $\mathfrak{A}_2$ being a positive operator form over the language $\mathcal{L}_2$ rather than $\mathcal{L}_1$. This is needed in order to be able to interpret a $\text{(Fix}_{t \in P_{\mathfrak{A}_2}}$ inference, but it also makes it more difficult to remove
cuts partially. Recall that in order to be able to use theorem 3.14, we first had to partially remove cuts in $\text{SID}_\infty^2$ before doing an asymmetric interpretation (this was needed to make the proof by induction of theorem 3.14 work). Similarly, $\hat{\text{ID}}_\infty^2$ needs first to partially remove cuts, and because of the existence of rules of inferences such as (#) this is only possible by doing a partial cut-elimination that involves a cut-reduction for formulas of transfinite rank (compare lemma 3.9). In contrast to this, we were able to avoid such cut-reductions for $\text{SID}_\infty^2$ so that it was needed only once in the very end for $\text{SID}_0^\omega$. We refer to the references for more details on the proof-theoretic analysis of $\hat{\text{ID}}_n$ for $n < \omega$ (yielding $|\hat{\text{ID}}_{<\omega}| = \Gamma_0$) and the generalisation to the transfinite.

**Transfinite stratification** The equality $\phi_{\varepsilon_0}(0) = |\hat{\text{ID}}_1| = |\text{SID}_n| = |\text{SID}_{<\omega}|$ (with $n < \omega$) established here still leaves the question open concerning the relationship of stratification to iteration. For this, we refer to [JP15] where a generalisation of stratification to the transfinite gives an answer to it. The following picture captures line by line some aspects of this relationship and we refer again to [JP15] for the meaning and characterisation of the last three rows.
