

# How to Normalize the Jay

Dieter Probst \*      Thomas Studer \*

## Abstract

In this note we give an elementary proof of the strong normalization property of the J combinator by providing an explicit bound for the maximal length of the reduction paths of a term. This result shows nicely that in the theorem of Toyama, Klop and Barendregt on completeness of unions of left linear term rewriting systems, disjointness is essential.

*Keywords:* Term rewriting systems; Combinatory logic; Strong normalization

## 1 Introduction

The combinators I and J with their reduction rules  $Ia \rightarrow a$  and  $Jabcd \rightarrow ab(adc)$  were introduced by Rosser [2] in 1935. These two combinators are of particular interest since they form a basis for the  $\lambda$ -calculus (cf. e.g. Barendregt [1]).

In combinatory logic, it is natural to ask whether a certain system is strongly normalizing, i.e. whether there exists no term with an infinite reduction path. Many standard combinators such as K, B, C and I are strongly normalizing, with the notable exception of S. But surprisingly, it appears to be unknown whether the reduction system generated by the combinator J is strongly normalizing.

In this note, we prove the strong normalization property of the J combinator by providing an explicit bound for the maximal length of the reduction paths of a term. Or, in the words of Smullyan [3], we show that binary trees with jaybirds sitting on their leaves strongly normalize.

## 2 Notation

Let  $L_J$  denote the language containing countably many variables  $x_1, x_2, \dots$ , the constant symbol  $J$  and the binary function symbol  $\cdot$  (application). As usual, the constant  $J$  and every variable are  $L_J$ -terms, and if  $s$  and  $t$  are  $L_J$ -terms then also  $(s \cdot t)$ . We write  $st$  for  $(s \cdot t)$  and adopt the convention of association to the left, i.e.  $s_1 \dots s_n$  stands for  $(\dots (s_1 s_2) \dots s_n)$ . By  $\mathcal{C}_J$  we denote the set of all  $L_J$ -terms, and by  $\mathcal{C}_J^0$  the set of all closed  $L_J$ -terms, i.e. the  $L_J$ -terms which contain no variables.

**Definition 1.**  $\rightarrow \subseteq \mathcal{C}_J \times \mathcal{C}_J$  is the smallest relation satisfying

- (1)  $Jabcd \rightarrow ab(adc)$  for all  $L_J$ -terms  $a, b, c, d$ .
- (2) If  $s, s', t$  are  $L_J$ -terms and  $s \rightarrow s'$ , then also  $st \rightarrow s't$  and  $ts \rightarrow ts'$ .

If  $s \rightarrow t$  holds for two terms  $s$  and  $t$ , we say that  $s$  *reduces to*  $t$ .

**Definition 2.** An *infinite reduction path* is an infinite sequence of  $L_J$ -terms  $(t)_{n \in \mathbb{N}}$  such that  $t_n \rightarrow t_{n+1}$  for all  $n \in \mathbb{N}$ .

**Definition 3.** An  $L_J$ -term  $t$  is *strongly normalizable*, if there is no infinite reduction path starting with  $t$ . An  $L_J$ -term  $t$  is said to be in *normal form*, if there is no  $L_J$ -term  $t'$  such that  $t \rightarrow t'$ .

Whenever  $s \rightarrow t$  holds, there is a subterm  $s'$  of  $s$  of the form  $Jabcd$  which reduces to a subterm  $ab(adc)$  of  $t$ . The following definition gives us a tool to indicate the particular occurrence of the subterm  $s'$  which gets reduced.

**Definition 4.** Let  $\mathcal{W}$  be the set of all finite words over the alphabet  $\{l, r\}$ . The empty word is denoted by  $\epsilon$ . For every  $w \in \mathcal{W}$  we define a function  $f_w : \mathcal{C}_J^0 \rightarrow \mathcal{C}_J^0 \cup \{\perp\}$  where  $\perp \notin \mathcal{C}_J^0$  by

$$\begin{aligned} f_\epsilon(t) &:= t, \\ f_{lw}(J) &:= \perp, \\ f_{rw}(J) &:= \perp, \\ f_{lw}(st) &:= f_w(s), \\ f_{rw}(st) &:= f_w(t). \end{aligned}$$

In the sequel we often write  $(t)_w$  for  $f_w(t)$ .

**Definition 5.** An  $L_J$ -term of the form  $Jabcd$  is called a *redex with contractum*  $ab(adc)$ . If  $w \in \mathcal{W}$ , we write  $t \rightarrow_w t'$  if there is a redex  $r$  with contractum  $r'$  such that  $(t)_w \equiv r$  and  $(t')_w \equiv r'$ .

The following lemmas are trivial consequences of Definition 1.

**Lemma 6.** *Every  $t \in \mathcal{C}_J$  is strongly normalizable if and only if every  $t \in \mathcal{C}_J^0$  is strongly normalizable.*

**Lemma 7.** *For every  $r \in \mathcal{C}_J^0$  we have: if there exist  $r' \in \mathcal{C}_J^0$  and  $w \in \mathcal{W}$  so that  $r \rightarrow_w r'$  and  $w \neq \epsilon$ , then there are  $s, t, s', t' \in \mathcal{C}_J^0$  and  $w' \in \mathcal{W}$  such that  $r \equiv st$  and either*

- (1)  $w = lw'$  and  $s \rightarrow_{w'} s'$  and  $r' \equiv s't$ , or
- (2)  $w = rw'$  and  $t \rightarrow_{w'} t'$  and  $r' \equiv st'$ .

### 3 Normalization

The next definition is the crucial step in our normalization proof. We introduce a weighting function  $|\cdot|$  which assigns to every  $\mathbf{L}_J$ -term an upper bound for the maximal length of its reduction paths.

**Definition 8.** We define  $|\cdot| : \mathcal{C}_J^0 \rightarrow \mathbb{N}$  recursively by the following clauses:

$$|r| := \begin{cases} 1, & \text{if } r \equiv J, \\ |t| + 2^{|(s)_l|} + |s|, & \text{if } r \equiv st \text{ and } s \not\equiv J, \\ |t| + |s|, & \text{if } r \equiv st \text{ and } s \equiv J. \end{cases}$$

Observe that this function does not satisfy the replacement property, meaning we find terms  $s, s', t$  in  $\mathcal{C}_J^0$  so that both  $|s| > |s'|$  and  $|st| < |s't|$  hold. For example, choose  $s \equiv J(J(J(J(J))))$ ,  $s' \equiv JJJ$  and  $t \equiv J$ . Then we obviously have  $|s| = 6 > 5 = |s'|$  but also  $|st| = 9 < 10 = |s't|$ . The reason is that  $|(s)_l| = 1 < 2 = |(s')_l|$ . Please note that  $s \rightarrow s'$  does not hold in this example, cf. Theorem 10.

**Lemma 9.** *For all  $a, b, c, d \in \mathcal{C}_J^0$  we have:*

- (1)  $|Jabcd| > |ab(adc)|$ .
- (2)  $|Jabc| = |(Jabcd)_l| > |(ab(adc))_l| = |ab|$ .

*Proof.* Let  $a \not\equiv J$ . A straightforward calculation yields

$$|Jabcd| = |d| + 2^{|b|+2^1+|a|+1} + |c| + 2^{|a|+1} + |b| + 2^1 + |a| + 1$$

and

$$|ab(adc)| = |c| + 2^{|a|} + |d| + 2^{|(a)_l|} + |a| + 2^{|a|} + |b| + 2^{|(a)_l|} + |a|.$$

Because of  $|(a)_l| < |a|$  and  $n < 2^n$  ( $\forall n \in \mathbb{N}$ ) we have

$$2 \cdot 2^{|a|} + 2 \cdot 2^{|(a)_l|} + |a| < 2^{|a|+1} + 2^{|a|} + 2^{|a|} \leq 2^{|a|+2},$$

therefore Claim (1) is verified. (2) clearly holds since

$$|Jabc| = |c| + 2^{|a|+1} + |b| + 2^1 + |a| + 1,$$

and

$$|ab| = |b| + 2^{|(a)_l|} + |a|.$$

In the case  $a \equiv \mathbf{J}$  the expressions  $2^{|(a)_l|}$  do not appear in the above arguments and both claims hold as well.  $\square$

**Theorem 10.** *For every closed  $\mathbf{L}_J$ -term  $r$  we have: if there is a closed  $\mathbf{L}_J$ -term  $r'$  with  $r \rightarrow r'$ , then  $|r| > |r'|$  and also  $|(r)_l| \geq |(r')_l|$ .*

*Proof.* First, we note that since  $r$  contains a redex,  $r$  must be of the form  $st$ . Therefore we have  $(r)_l \neq \perp$ . We prove the theorem by induction on the definition of closed  $\mathbf{L}_J$ -terms. Consider the closed  $\mathbf{L}_J$ -term  $r \equiv st$  and suppose that the claim holds for  $s$  and  $t$ . If  $r \rightarrow_\epsilon r'$  the claim follows by Lemma 9. Otherwise, by Lemma 7, there exist  $w \in \mathcal{W}$  and  $s', t' \in \mathcal{C}_J^0$  so that either

- (1)  $r \rightarrow_{tw} r'$  and  $s \rightarrow_w s'$  and  $r' \equiv s't$ , or
- (2)  $r \rightarrow_{rw} r'$  and  $t \rightarrow_w t'$  and  $r' \equiv st'$ .

Assume we are in the first case. By the induction hypothesis we get  $|s| > |s'|$  and  $|(s)_l| \geq |(s')_l|$ , so that

$$|r| = |st| = |t| + 2^{|(s)_l|} + |s| > |t| + 2^{|(s')_l|} + |s'| = |s't| = |r'|.$$

Further, we obtain

$$|(r)_l| = |s| \geq |s'| = |(r')_l|.$$

In the second case the induction hypothesis yields  $|t| > |t'|$ , and we proceed as in the first case.  $\square$

**Corollary 11.** *Every  $\mathbf{L}_J$ -term is strongly normalizable.*

## 4 Conclusion

In this note we have proved a strong normalization theorem for the combinatory system generated by the combinator  $J$ . Since  $I$  and  $J$  form a basis for the  $\lambda$ -calculus our work shows that the following theorem of Toyama, Klop and Barendregt [4] does not apply in the context of combinatory logic: given two left-linear term rewriting systems  $R_1$  and  $R_2$ , then we have that  $R_1$  and  $R_2$  are complete (i.e. confluent and terminating) if and only if the disjoint union of  $R_1$  and  $R_2$  is complete. The reason why it does not apply is that there is a hidden application function in the two systems generated by  $I$  and  $J$ , respectively. In the combinatory logic built up from  $I$  and  $J$ , these two functions are identified, whereas in the disjoint union of the two system, these application functions are distinct. Therefore, the above theorem cannot be applied.
